## Chapter 6: Stochastic (Random) Processes

Let outcomes $\xi$ from $S$ be such that, for $\xi \in S$ we assign a function of time according to some rule:

$$
\mathrm{X}(\mathrm{t}, \xi) \text { where } \mathrm{t} \in \mathrm{I}
$$

1) The graph of $X(t, \xi)$ for a fixed $\xi$ is called a realization.
2) For each fixed $t_{k}$ the set $X\left(t_{k}, \xi\right)$ is a r.v.
$\Rightarrow$ Indexed family of r.v. $\Rightarrow$ Stochastic Process

- If the index set "I" is If "I" is continuous, then it is a continuous-time stochastic process.
- If discrete-time then, we have a discrete-time stochastic process.

## FIGURE 8.1

Savaral rel izafons di mardon posess

## Ex: 6.1 Random Binary Sequence

$\xi$ selected randomly in interval $S=[0,1] \quad b_{1} b_{2} \ldots$ binary expansion of $\xi$, then

$$
\xi=\sum_{i=1}^{\infty} b_{i} 2^{-i} ; \text { where } b_{i} \in\{0,1\}
$$

Define $\mathrm{X}(\mathrm{t}, \xi)=b_{\mathrm{n}} \quad \mathrm{n}=1,2, \ldots$ The result is a sequence of binary numbers.
Ex: 6.3 Find $P[X(1, \xi)=0]$ and $P[X(1, \xi)=0$ and $X(2, \xi)=1]$

$$
P[X(1, \xi)=0]=P[0 \leq \xi<1 / 2]=1 / 2
$$

$$
P[X(1, \xi)=0 \text { and } X(2, \xi)=1]=P[1 / 4 \leq \xi<1 / 2]=1 / 4
$$

Sequence of $k$ bits has subinterval of length $2^{-k}$.

## Ex: 6.2 Random Sinusoids

$$
\xi \text { in interval } \mathrm{S}=[-\pi, \pi]
$$

Define $\mathrm{Y}(\mathrm{t}, \xi)=\operatorname{Cos}(2 \pi \mathrm{t}+\xi)$
Time-shifted versions

(b)

Ex: 6.4 Find pdf of $X\left(\mathrm{t}_{0}, \xi\right)$ and $\mathrm{Y}\left(\mathrm{t}_{0}, \xi\right)$ of Ex: 6.2

- If $\cos \left(2 \pi \mathrm{t}_{0}\right)=0, \mathrm{X}\left(\mathrm{t}_{0}, \xi\right)=0 \Rightarrow f_{X\left(t_{0}\right)}(x)=\delta(x)$
- Else, $X\left(\mathrm{t}_{0}, \xi\right)$ is uniformly distributed in $\left[-\cos \left(2 \pi \mathrm{t}_{0}\right), \cos \left(2 \pi \mathrm{t}_{0}\right)\right]$, since $\mathrm{X}\left(\mathrm{t}_{0}, \xi\right)$ is uniformly distributed in $[-1,1]$

$$
f_{X\left(t_{0}\right)}(x)=\left\{\begin{array}{cc}
0 & \text { o.w. } \\
1 / 2\left|\cos \left(2 \pi t_{0}\right)\right| & x \leq\left|\cos \left(2 \pi t_{0}\right)\right|
\end{array}\right.
$$

Note: pdf of $X\left(\mathrm{t}_{0}, \xi\right)$ depends on $\mathrm{t}_{0}$.

FIGURE 6.3
|al ptitesicuscid ain renyen arplitade and (t) pdist stuscid sif rendan phase.

$\mathrm{Y}\left(\mathrm{t}_{0}, \xi\right)$ has an arcsine distribution (see Ex: 3.28).

$$
f_{Y\left(t_{0}\right)}(y)=\frac{1}{\pi \sqrt{1-y^{2}}}|y|<1
$$

Note: pdf of $\mathrm{Y}\left(\mathrm{t}_{0}, \xi\right)$ does not depend on $\mathrm{t}_{0}$.

## Random Process Specification:

Let $\mathrm{X}_{1}, \mathrm{X}_{2}, \ldots, \mathrm{X}_{\mathrm{k}}$ be k r.v.'s obtained by sampling a Random Process $\mathrm{X}(\mathrm{t}, \xi)$ at times $\mathrm{t}_{1}, \ldots, \mathrm{t}_{\mathrm{k}}$

$$
\mathrm{X}_{1}=\mathrm{X}\left(\mathrm{t}_{1}, \xi\right), \mathrm{X}_{2}=\mathrm{X}\left(\mathrm{t}_{2}, \xi\right), \ldots, \mathrm{X}_{\mathrm{k}}=\mathrm{X}\left(\mathrm{t}_{\mathrm{k}}, \xi\right)
$$

Then a stochastic (random) process is specified by the collection of $\mathrm{k}^{\text {th }}$ order joint cdf:

$$
F_{X_{1} \ldots X_{k}}\left(x_{1}, x_{2}, \ldots x_{k}\right)=P\left[X_{1} \leq x_{1}, X_{2} \leq x_{2}, \ldots, X_{k} \leq x_{k}\right]
$$

If Stochastic Process is discrete then pmf can be used to specify Stochastic Process

$$
p_{X_{1} \ldots X_{k}}\left(x_{1}, x_{2}, \ldots x_{k}\right)=P\left[X_{1}=x_{1}, X_{2}=x_{2}, \ldots, X_{k}=x_{k}\right]
$$

If Stochastic Process is continuous-valued the pdf can be used to specify Stochastic Process:

$$
f_{X_{1} \ldots X_{k}}\left(x_{1}, x_{2}, \ldots x_{k}\right)
$$

A Stochastic Process $\mathrm{X}(\mathrm{t})$ has independent increments if for any k and any choice of sampling instants:

$$
\begin{aligned}
& \mathrm{t}_{1}<\mathrm{t}_{2}<\ldots<\mathrm{t}_{\mathrm{k}}, \quad \text { the random variables } \\
& \mathrm{X}\left(\mathrm{t}_{2}\right)-\mathrm{X}\left(\mathrm{t}_{1}\right) \ldots \mathrm{X}\left(\mathrm{t}_{\mathrm{k}}\right)-\mathrm{X}\left(\mathrm{t}_{\mathrm{k}-1}\right) \quad \text { are independent }
\end{aligned}
$$

Then the joint pdf (pmf) of $X\left(t_{1}\right) \ldots X\left(t_{k}\right)$ is given by the product of marginal pdf (pmf).

A Stochastic Process is Markov if the future of the process given the present is independent of the past:

$$
\begin{gathered}
f_{X\left(t_{k}\right)}\left(x_{k} \mid X\left(t_{k-1}\right)=x_{k-1}, \ldots, X\left(t_{1}\right)=x_{1}\right) \\
=f_{X\left(t_{k}\right)}\left(x_{k} \mid X\left(t_{k-1}\right)=x_{k-1}\right)
\end{gathered}
$$

If $\mathrm{X}(\mathrm{t})$ is continuous, but for discrete $\mathrm{X}(\mathrm{t})$ the expression becomes

$$
\begin{aligned}
P\left[X\left(t_{k}\right)\right. & \left.=x_{k} \mid X\left(t_{k-1}\right)=x_{k-1}, \ldots, X\left(t_{1}\right)=x_{1}\right] \\
& =P\left[X\left(t_{k}\right)=x_{k} \mid X\left(t_{k-1}\right)=x_{k-1}\right]
\end{aligned}
$$

## Mean function:

$$
m_{X}(t)=E[X(t)]=\int_{-\infty}^{\infty} x f_{X(t)}(x) d x
$$

In general the mean function is a function of time.

## Autocorrelation function (joint moment):

$$
R_{X}\left(t_{1}, t_{2}\right)=E\left[X\left(t_{1}\right) X\left(t_{2}\right)\right]=\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x y f_{X\left(t_{1}\right) X\left(t_{2}\right)}(x, y) d x d y
$$

Autocovariance function:

$$
\begin{aligned}
C_{X}\left(t_{1}, t_{2}\right) & =E\left[\left(X\left(t_{1}\right)-m_{X}\left(t_{1}\right)\right)\left(X\left(t_{2}\right)-m_{X}\left(t_{2}\right)\right)\right] \\
& =R_{X}\left(t_{1}, t_{2}\right)-m_{X}\left(t_{1}\right) m_{X}\left(t_{2}\right)
\end{aligned}
$$

Variance of $X(t)$ :

$$
\sigma_{X(t)}^{2}=\operatorname{VAR}[X(t)]=E\left[\left(X\left(t_{1}\right)-m_{X}\left(t_{1}\right)\right)^{2}\right]=C_{X}(t, t)
$$

## Correlation Coefficient:

$$
\rho_{X}\left(t_{1}, t_{2}\right)=\frac{C_{X}\left(t_{1}, t_{2}\right)}{\sqrt{C_{X}\left(t_{1}, t_{1}\right) C_{X}\left(t_{2}, t_{2}\right)}} \quad \text { with the property: } \quad\left|\rho_{X}\left(t_{1}, t_{2}\right)\right| \leq 1
$$

Ex: 6.6 Let $\mathrm{X}(\mathrm{t})=\mathrm{Acos} 2 \pi \mathrm{t}$. Find mean, autocorrelation and autocovariance $m_{X}(t)=E[A \cos 2 \pi t]=E[A] \cos 2 \pi t$

Note: The mean function is time-dependent.

$$
\begin{aligned}
& R_{X}\left(t_{1}, t_{2}\right)=E\left[A \cos 2 \pi t_{1} A \cos 2 \pi t_{2}\right]=E\left[A^{2}\right] \cos 2 \pi t_{1} \cos 2 \pi t_{2} \\
& \begin{aligned}
C_{X}\left(t_{1}, t_{2}\right) & =R_{X}\left(t_{1}, t_{2}\right)-m_{X}\left(t_{1}\right) m_{X}\left(t_{2}\right)=\left\{E\left[A^{2}\right]-E[A]^{2}\right\} \cos 2 \pi t_{1} \cos 2 \pi t_{2} \\
& =\operatorname{VAR}[A] \cos 2 \pi t_{1} \cos 2 \pi t_{2}
\end{aligned}
\end{aligned}
$$

Ex: 6.7 Let $X(t)=\cos (w t+\theta)$, where $\theta$ is uniformly distributed in $(-\pi, \pi)$. Let us find mean, autocorrelation and autocovariance.

$$
\begin{aligned}
& m_{X}(t)=E[\cos (w t+\theta)]=\frac{1}{2 \pi} \int_{-\pi}^{\pi} \cos (w t+\theta) d \theta=0 \\
& \begin{aligned}
C_{X}\left(t_{1}, t_{2}\right) & =R_{X}\left(t_{1}, t_{2}\right)=E\left[\cos \left(w t_{1}+\theta\right) \cos \left(w t_{2}+\theta\right)\right] \\
& =\frac{1}{2 \pi} \int_{-\pi}^{\pi} \frac{1}{2}\left\{\cos \left(w\left(t_{1}-t_{2}\right)\right)+\cos \left(w\left(t_{1}+t_{2}\right)+2 \theta\right)\right\} d \theta \\
& =\frac{1}{2} \cos w\left(t_{1}-t_{2}\right) \quad \text { See Appendix } A
\end{aligned}
\end{aligned}
$$

Note: $\mathrm{m}_{\mathrm{X}}(\mathrm{t})$ is constant and $\mathrm{C}_{\mathrm{X}}\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right)$ depends only on $\left|\mathrm{t}_{1}-\mathrm{t}_{2}\right|$.
Gaussian Random Process: $\mathrm{X}(\mathrm{t})$ is a Gaussian S.P. if the samples $\mathrm{X}_{1}=\mathrm{X}\left(\mathrm{t}_{1}\right)$, $\ldots, \mathrm{X}_{\mathrm{k}}=\mathrm{X}\left(\mathrm{t}_{\mathrm{k}}\right)$ are jointly Gaussian with

$$
f_{X_{1} X_{2} \ldots X_{k}}\left(x_{1}, \ldots, x_{k}\right)=\frac{1}{(2 \pi)^{k / 2}|K|^{1 / 2}} \exp \left\{-\frac{1}{2}(\underline{x}-\underline{m})^{T} K^{-1}(\underline{x}-\underline{m})\right\}
$$

where

$$
\underline{m}=\left[\begin{array}{c}
m_{X}\left(t_{1}\right) \\
\vdots \\
m_{X}\left(t_{k}\right)
\end{array}\right] \quad K=\left[\begin{array}{cccc}
C_{X}\left(t_{1}, t_{1}\right) & C_{X}\left(t_{1}, t_{2}\right) & \cdots & C_{X}\left(t_{1}, t_{k}\right) \\
C_{X}\left(t_{2}, t_{1}\right) & C_{X}\left(t_{2}, t_{2}\right) & \cdots & C_{X}\left(t_{2}, t_{k}\right) \\
\vdots & \vdots & & \vdots \\
C_{X}\left(t_{k}, t_{1}\right) & \cdots & & C_{X}\left(t_{k}, t_{k}\right)
\end{array}\right]
$$

Ex 6.8 $\mathrm{X}_{\mathrm{n}}$ is iid Gaussian r.v. with m and $\sigma^{2}$, then

$$
K=\left[\begin{array}{cccc}
\sigma^{2} & 0 & \cdots & 0 \\
0 & \ddots & 0 & \vdots \\
\vdots & 0 & \ddots & 0 \\
0 & \cdots & 0 & \sigma^{2}
\end{array}\right]=\sigma^{2} I \quad \text { Because: } C_{X}\left(t_{i}, t_{j}\right)=\sigma^{2} \delta_{i j}
$$

Then:

$$
\begin{gathered}
f_{X_{1} X_{2} \ldots X_{k}}\left(x_{1}, \ldots, x_{k}\right)=\frac{1}{\left(2 \pi \sigma^{2}\right)^{k / 2}} \exp \left\{-\sum_{i=1}^{k}\left(x_{i}-\underline{m}\right)^{2} / 2 \sigma^{2}\right\} \\
=f_{X_{1}}\left(x_{1}\right) f_{X_{2}}\left(x_{2}\right) \cdots f_{X_{k}}\left(x_{k}\right)
\end{gathered}
$$

## Two or more variable Random Process:

1. For a pair of S.P. $\mathrm{X}(\mathrm{t})$ and $\mathrm{Y}\left(\mathrm{t}^{\prime}\right)$ all possible joint density functions must be specified for all choices of $t_{1}, \ldots, t_{k}$ and $t_{1}{ }^{\prime}, \ldots, t_{k}{ }^{\prime}$.
2. $\mathrm{X}(\mathrm{t})$ and $\mathrm{Y}\left(\mathrm{t}^{\prime}\right)$ are independent iff the vector r.v. $\mathbf{X}$ and $\mathbf{Y}$ are independent for all $\mathrm{k}, \mathrm{j}$ and all choices of $\mathrm{t}_{1}, \ldots, \mathrm{t}_{\mathrm{k}}, \mathrm{t}_{1}{ }^{\prime}, \ldots, \mathrm{t}_{\mathrm{k}}{ }^{\prime}$.
3. Crosscorrelation: $\mathrm{R}_{\mathrm{XY}}\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right)=\mathrm{E}\left[\mathrm{X}\left(\mathrm{t}_{1}\right) \mathrm{Y}\left(\mathrm{t}_{2}\right)\right]$
$\mathrm{X}(\mathrm{t})$ and $\mathrm{Y}(\mathrm{t})$ processes are orthogonal if $\mathrm{R}_{\mathrm{XY}}\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right)=0$ for all $\mathrm{t}_{1}$ and $t_{2}$
4. Cross-Covariance: $\mathrm{C}_{\mathrm{XY}}\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right)=\mathrm{R}_{\mathrm{XY}}\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right)-\mathrm{m}_{\mathrm{X}}\left(\mathrm{t}_{1}\right) \mathrm{m}_{\mathrm{Y}}\left(\mathrm{t}_{2}\right)$ $\mathrm{X}(\mathrm{t})$ and $\mathrm{Y}(\mathrm{t})$ are uncorrelated if $\mathrm{C}_{\mathrm{XY}}\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right)=0$ for all $\mathrm{t}_{1}$ and $\mathrm{t}_{2}$
Ex: 6.9 Given a process with $X(t)=\cos (w t+\theta)$ and $Y(t)=\sin (w t+\theta)$, where $\theta$ is uniformly distributed in $[-\pi, \pi]$. Find cross-covariance.

$$
\begin{aligned}
R_{X Y}\left(t_{1}, t_{2}\right) & =E\left[\cos \left(w t_{1}+\theta\right) \sin \left(w t_{2}+\theta\right)\right] \\
= & E\left[-\frac{1}{2} \sin \left(w\left(t_{1}-t_{2}\right)\right)+\frac{1}{2} \sin \left(w\left(t_{1}+t_{2}\right)+2 \theta\right)\right] \\
& =-\frac{1}{2} \sin \left(w\left(t_{1}-t_{2}\right)\right)
\end{aligned}
$$

Ex: 6.10 Given an additive noise channel with a model: $Y(t)=X(t)+N(t)$ Find cross-correlation. Assume that $\mathrm{X}(\mathrm{t})$ and $\mathrm{N}(\mathrm{t})$ are independent

$$
\begin{aligned}
R_{X Y}\left(t_{1}, t_{2}\right) & =E\left[X\left(t_{1}\right) Y\left(t_{2}\right)\right]=E\left[X\left(t_{1}\right)\left\{X\left(t_{2}\right)+N\left(t_{2}\right)\right\}\right] \\
R_{X Y}\left(t_{1}, t_{2}\right) & =E\left[X\left(t_{1}\right) X\left(t_{2}\right)\right]+E\left[X\left(t_{1}\right) N\left(t_{2}\right)\right] \\
& =R_{X}\left(t_{1}, t_{2}\right)+E\left[X\left(t_{1}\right)\right] E\left[N\left(t_{2}\right)\right] \\
& =R_{X}\left(t_{1}, t_{2}\right)+m_{X}\left(t_{1}\right) m_{N}\left(t_{2}\right)
\end{aligned}
$$

Examples of Discrete-Time Stochastic Processes:
Given iid Stochastic Process: $X_{n}$ : discrete iid r.v. with common, $m, \sigma^{2}$ Then, $\mathrm{X}_{\mathrm{n}}$ - sequence is called iid R.P. and for any time instants $\mathrm{n}_{1}, \ldots, \mathrm{n}_{\mathrm{k}}$

$$
\begin{aligned}
F_{X_{1} \ldots X_{k}}\left(x_{1}, \ldots, x_{k}\right) & =P\left[X_{1} \leq x_{1}, \ldots, X_{k} \leq x_{k}\right] \\
& =F_{X}\left(x_{1}\right) F_{X}\left(x_{2}\right) \cdots F_{X}\left(x_{k}\right)
\end{aligned}
$$

The mean of iid S.P.:

$$
\mathrm{m}_{\mathrm{X}}(\mathrm{n})=\mathrm{E}\left[\mathrm{X}_{\mathrm{n}}\right]=\mathrm{m} \quad \text { for all } \mathrm{n} ; \quad \text { Constant mean }
$$

$$
\begin{aligned}
\text { if } \quad \begin{aligned}
n_{1} \neq n_{2}: \quad C_{X}\left(n_{1}, n_{2}\right) & =E\left(\left(X_{n_{1}}-m\right)\left(X_{n_{2}}-m\right)\right] \\
& =E\left[X_{n_{1}}-m\right] E\left[X_{n_{2}}-m\right]=0 \\
\text { if } \quad n_{1}=n_{2}: \quad C_{X}(n, n) & =E\left[\left(X_{n}-m\right)^{2}\right]=\sigma^{2}
\end{aligned}
\end{aligned}
$$

Because: $C_{X}\left(n_{1}, n_{2}\right)=R_{X}\left(n_{1}, n_{2}\right)-m^{2}$, which results in:

$$
\begin{aligned}
& C_{X}\left(n_{1}, n_{2}\right)=R_{X}\left(n_{1}, n_{2}\right)-m^{2} \\
& \quad \Rightarrow R_{X}\left(n_{1}, n_{2}\right)=C_{X}\left(n_{1}, n_{2}\right)+m^{2}
\end{aligned}
$$

Ex: 6.11 Bernoulli R.P. : i.i.d. Bernoulli R.V. $I_{n}$ from a set $\{0,1\}$, where $\mathrm{I}_{\mathrm{n}}$ : Indicator function for the event a light bulb fails \& replaced on day n .

\end{aligned}
$$

Find Prob. that first 4-bits
(3) are 1001:

(b)

$$
P\left[I_{1}=1, I_{2}=0, I_{3}=0, I_{4}=1\right]=p(1-p)(1-p) p=p^{2}(1-p)^{2}
$$

## Sum Process:

$$
\text { Let } \begin{aligned}
\mathrm{S}_{\mathrm{n}} & =\mathrm{X}_{1}+\mathrm{X}_{2}+\ldots+\mathrm{X}_{\mathrm{n}} \quad \mathrm{n}=1,2, \ldots \\
& =\mathrm{S}_{\mathrm{n}-1}+\mathrm{X}_{\mathrm{n}},
\end{aligned}
$$

$\mathrm{pmf} / \mathrm{pdf}$ of $\mathrm{S}_{\mathrm{n}}$ is found by convolution or characteristic equation methods. The block diagram shows a counting process:

```
FIGURE 6.6

So =0, caibegererded
inthskey.
```

$$
\begin{aligned}
& E\left[S_{n}\right]=m_{S}(n)=n E[X]=n m \\
& \qquad \begin{aligned}
\sigma_{S_{n}}^{2}=n & \sigma_{X}^{2}=n \sigma^{2} \\
C_{S}(n, k) & =E\left[\left(S_{n}-E\left[S_{n}\right]\right)\left(S_{k}-E\left[S_{k}\right]\right)\right] \\
& =E\left[\left(S_{n}-n m\right)\left(S_{k}-k m\right)\right] \\
& =E\left[\left\{\sum_{i=1}^{n}\left(X_{i}-m\right)\right\}\left\{\sum_{j=1}^{k}\left(X_{k}-m\right)\right\}\right] \\
& =\sum_{i=1}^{n} \sum_{j=1}^{k} \underbrace{E\left[\left(X_{i}-m\right)\left(X_{j}-m\right)\right]}_{C_{X}(i, j)=\sigma^{2} \delta_{i j}}
\end{aligned}
\end{aligned}
$$

which yields:

$$
C_{S}(n, k)=\sum_{i=1}^{\min \{n, k\}} C_{X}(i, i)=\min (n, k) \sigma^{2}
$$

## Examples of Continuous-Time Stochastic Processes

(As a limit of Discrete-Time Stochastic Processes)
Poisson Process

- Events occur randomly at a rate $\lambda$
- Let $\mathrm{N}(\mathrm{t})$ be the number of occurrences in time interval $[0, \mathrm{t}]$. $\mathrm{N}(\mathrm{t})$ is nondecreasing, integer-valued, continuous-time R.P.
- Let $[0, \mathrm{t}]$ be divided into n -intervals of duration $\delta=\mathrm{t} / \mathrm{n}$ and assume

1) Probability of more than one event occurring in a subinterval is negligible.

## $\Rightarrow$ Bernoulli Trial

2) Event occurrences in a subinterval is independent of activities in other subintervals

## $\Rightarrow$ Bernoulli Trials are Independent

$\Rightarrow \mathrm{N}(\mathrm{t})$ is counting process that counts number of success in n-trials. Keeping $\mathrm{np}=\lambda \mathrm{t}$ fixed, let $\mathrm{n} \rightarrow \infty$ and $\mathrm{p} \rightarrow 0$. Then we have a poisson distribution with parameter $\lambda t$
$\Rightarrow$ Poisson Process $\mathrm{N}(\mathrm{t})$ in the interval [0,t] has Poisson distribution with

$$
P[N(t)=k]=\frac{(\lambda t)^{2}}{k!} e^{-\lambda t} \quad \text { for } k=0,1,2, \cdots
$$

The independent and stationary increments property leads us to write for $\mathrm{t}_{1}<\mathrm{t}_{2}$ :

$$
\begin{aligned}
P\left[N\left(t_{1}\right)=i, N\left(t_{2}\right)=j\right] & =P\left[N\left(t_{1}\right)=i\right] P\left[N\left(t_{2}\right)-N\left(t_{1}\right)=j-i\right] \\
& =P\left[N\left(t_{1}\right)=i\right] P\left[N\left(t_{2}-t_{1}\right)=j-i\right] \\
& =\frac{\left(\lambda t_{1}\right)^{i}}{i!} e^{-\lambda t_{1}} \cdot \frac{\left(\lambda\left(t_{2}-t_{1}\right)\right)^{j-i}}{(j-i)!} e^{-\lambda\left(t_{2}-t_{1}\right)}
\end{aligned}
$$

Autocovariance of $\mathrm{N}(\mathrm{t})$ for $\mathrm{t}_{1}<\mathrm{t}_{2}$ :

$$
\begin{aligned}
C_{N}\left(t_{1}, t_{2}\right) & =E\left[\left(N\left(t_{1}\right)-\lambda t_{1}\right)\left(N\left(t_{2}\right)-\lambda t_{2}\right)\right] \\
& =E\left[\left(N\left(t_{1}\right)-\lambda t_{1}\right)\left\{N\left(t_{2}\right)-N\left(t_{1}\right)-\lambda t_{2}+\lambda t_{1}+N\left(t_{1}\right)-\lambda t_{1}\right\}\right] \\
C_{N}\left(t_{1}, t_{2}\right) & =\underbrace{E\left[\left(N\left(t_{1}\right)-\lambda t_{1}\right)\right] E\left[\left(N\left(t_{2}-t_{1}\right)-\lambda\left(t_{2}-t_{1}\right)\right)\right]+\operatorname{VAR}\left[N\left(t_{1}\right)\right]}_{0} \\
& =\operatorname{VAR}\left[N\left(t_{1}\right)\right]=\lambda t_{1} \quad \text { Since } t_{1} \leq t_{2}
\end{aligned}
$$

In general we have:

$$
C_{N}\left(t_{1}, t_{2}\right)=\lambda \min \left\{t_{1}, t_{2}\right\}
$$

Ex: 6.19 15 Inquires/minute; A Poisson Process Find $P[N(10)=3$ and $N(60)-$ $\mathrm{N}(45)=2]$

Poisson $\Rightarrow$ indep increment \& stationary increment

$$
\begin{aligned}
P[N(10)=3 \text { and } N(60)-N(45)=2]= & P[N(10)=3] P[N(60)-N(45)=2] \\
& =P[N(10)=3] P[N(60-45)=2] \\
& =\frac{(10 / 4)^{3} e^{-10 / 4}}{3!} \frac{(15 / 4)^{2} e^{-15 / 4}}{2!}
\end{aligned}
$$

## Ex: 6.22 Random Telegraph Signal

$\mathrm{X}(\mathrm{t})$ is $\pm 1 \quad \mathrm{P}[\mathrm{X}(0)= \pm 1]=1 / 2 \quad \mathrm{X}(\mathrm{t})$ is Poisson with rate $\alpha$
Probability mass function (pmf):

P[X(t)= \pm 1]=P[X(t)= \pm 1 \mid X(0)=1] P[X(0)=1]+P[X(t)= \pm 1 \mid X(0)=-1] P[X(0)=-1]
$$

Since $\mathrm{X}(\mathrm{t})$ has same polarity as $\mathrm{X}(0)$ only when even number of events

$$
\begin{aligned}
P[X(t)= \pm 1 \mid X(0)=1]= & P[N(t)=\text { even int eger }] \\
& =\sum_{j=0}^{\infty} \frac{(\alpha t)^{2 j}}{(2 j)!} e^{-\alpha t} \\
& =e^{-\alpha t} \frac{1}{2}\left\{e^{\alpha t}+e^{-\alpha t}\right\}=\frac{1}{2}\left\{1+e^{-2 \alpha t}\right\}
\end{aligned}
$$

$X(t)$ and $X(0)$ differ in sign with odd number of events:

$$
\begin{aligned}
P[X(t)= \pm 1 \mid X(0)=1] & =\sum_{j=0}^{\infty} \frac{(\alpha t)^{j+1}}{(2 j+1)!} e^{-\alpha t} \\
& =e^{-\alpha t} \frac{1}{2}\left\{e^{\alpha t}+-e^{-\alpha t}\right\}=\frac{1}{2}\left\{1-e^{-2 \alpha t}\right\}
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
& P[X(t)=1]=\frac{1}{2} \cdot \frac{1}{2}\left\{1+e^{-2 \alpha t}\right\}+\frac{1}{2} \cdot \frac{1}{2}\left\{1-e^{-2 \alpha t}\right\}=\frac{1}{2} \\
& P[X(t)=-1]=1-P[X(t)=1]=\frac{1}{2}
\end{aligned}
$$

Thus signal is equally likely to be $\pm 1$. Next we find the mean, variance and autocovariance functions.

$$
\begin{aligned}
& m_{X}(t)=(1) \cdot P[X(t)=1]+(-1) \cdot P[X(t)=-1]=0 \\
& \operatorname{VAR}[X(t)]=E\left[X(t)^{2}\right]=(1)^{2} \cdot P[X(t)=1]+(-1)^{2} \cdot P[X(t)=-1]=1 \\
& C_{X}\left(t_{1}, t_{2}\right)=E\left[X\left(t_{1}\right) X\left(t_{2}\right)\right]=(1) P\left[X\left(t_{1}\right)=X\left(t_{2}\right)\right]+(-1) P\left[X\left(t_{1}\right) \neq X\left(t_{2}\right)\right] \\
& \\
& \quad=\frac{1}{2}\left\{1+e^{\left.-2 \alpha t_{2}-t_{1}\right\}}\right\}
\end{aligned}
$$

Note: Time samples of $\mathrm{X}(\mathrm{t})$ become less correlated as time between them increases. Also it does not matter which time is greater

Ex: 6.23 Filtered Poisson Impulse Train: Zero at $\mathrm{t}=0$ and increases by one unit at random arrival times: $\mathrm{S}_{\mathrm{j}}, \mathrm{i}=1,2, \ldots$

$$
N(t)=\sum_{i=1}^{\infty} u\left(t-S_{i}\right) \quad N(0)=0
$$

We can view $\mathrm{N}(\mathrm{t})$ as the integral of a train of delta functions

$$
Z(t)=\sum_{i=1}^{\infty} \delta\left(t-S_{i}\right)
$$

We can obtain other continuous-time processes by replacing the step function by another function $\mathrm{h}(\mathrm{t})$-Figure 6.10b.

## FIGURE 6.10a

Palsmprosass ss itegal of unir of cella finctisrs.

FIGURE 5.10 b
Filesastranol dala butions

Ex: 6.24 Shot Noise: $h(t)$ is the current pulse generator when a photoelectron hits a detector.

$$
X(t)=\sum_{i=1}^{\infty} h\left(t-S_{i}\right)
$$

Find expected value: $E[X(t)]=E[E[X(t) \mid N(t)]$, where $\mathrm{N}(\mathrm{t})$ is number of impulses that occurred up to time $t$

$$
E[E[X(t) \mid N(t)=k]]=E\left[\sum_{j=1}^{\infty} h\left(t-S_{j}\right)\right]=\sum_{j=1}^{\infty} E\left[h\left(t-S_{j}\right)\right]
$$

Since independent and uniformly distributed in interval [0,t]:

$$
E\left[h\left(t-S_{j}\right)\right]=\int_{0}^{t} h(t-s) \frac{d s}{t}=\frac{1}{t} \int_{0}^{t} h(u) d u
$$

Thus:

$$
E[X(t) \mid N(t)=k]=\frac{k}{t} \int_{0}^{t} h(u) d u
$$

and

$$
E[X(t) \mid N(t)]=\frac{N(t)}{t} \int_{0}^{t} h(u) d u
$$

Finally, we obtain:

$$
\begin{aligned}
E[X(t)] & =E[E[X(t) \mid N(t)]]=\frac{E[N(t)]}{t} \int_{0}^{t} h(u) d u \\
& =\lambda \int_{0}^{t} h(u) d u \quad \text { where } \quad E[N(t)]=\lambda t
\end{aligned}
$$

The integral is finite, as t becomes large $\mathrm{E}[\mathrm{N}(\mathrm{t})] \rightarrow$ constant
(Skip Wiener Process and Brownian Motion)

## Stationary Random Process (Strictly Stationary)

- Nature of randomness stays unchanged with time (Independent of time origin).
- A discrete-time or continuous S.P. X(t) is stationary if the joint distribution of any set of samples does not depend on the time origin:

$$
F_{X\left(t_{1}\right) \cdots X\left(t_{k}\right)}\left(x_{1}, \ldots, x_{k}\right)=F_{X\left(t_{1}+\tau\right) \cdots X\left(t_{k}+\tau\right)}\left(x_{1}, \ldots, x_{k}\right)
$$

for all $\tau$, all $k$, and all choices of $t_{1}, \ldots, t_{k}$

- First-order cdf of a stationary R.P. must be independent of t .

$$
\begin{aligned}
& F_{X(t)}(x)=F_{X(t+\tau)}(x)=F_{X}(x) \quad \forall t, \forall \tau \\
& m_{X(t)}=E[X(t)]=m \quad \forall t \\
& \operatorname{VAR}[X(t)]=\sigma^{2} \quad \forall t
\end{aligned}
$$

- $2^{\text {nd }}$ order cdf of a stationary R.P. can depend only on the time difference between the samples:

$$
\begin{array}{ll}
F_{X}\left(t_{1}\right) X\left(t_{2}\right)\left(x_{1}, x_{2}\right)=F_{X\left(t_{1}\right) X\left(t_{2}-t_{1}\right)}\left(x_{1}, x_{2}\right) \quad \forall t_{1}, t_{2} \\
R_{X}\left(t_{1}, t_{2}\right)=R_{X}\left(t_{2}-t_{1}\right)=R_{X}(\tau) & \text { where } \tau=t_{2}-t \\
C_{X}\left(t_{1}, t_{2}\right)=C_{X}\left(t_{2}-t_{1}\right)=C_{X}(\tau) & \text { where } \tau=t_{2}-t
\end{array}
$$

Ex: 6.26 Show i.i.d. R.P. is stationary:

$$
\begin{gathered}
F_{X\left(t_{1}\right) \cdots X\left(t_{k}\right)}\left(x_{1}, x_{2}, \ldots x_{k}\right)=F_{X}\left(x_{1}\right) F_{X}\left(x_{2}\right) \cdots F_{X}\left(x_{k}\right) \\
=F_{X\left(t_{1}+\tau\right) \cdots X\left(t_{k}+\tau\right)}\left(x_{1}, \cdots x_{k}\right)
\end{gathered}
$$

$$
\text { for all } k, t_{1}, \ldots, t_{k} \text {. }
$$

Therefore, i.i.d. R.P. is stationary.
Ex: 6.27 Is sum process a discrete-time stationary process?

$$
\begin{aligned}
& \mathrm{S}_{\mathrm{n}}=\mathrm{X}_{1}+\mathrm{X}_{2}+\ldots+\mathrm{X}_{\mathrm{n}} \quad \text { where } \mathrm{X}_{\mathrm{i}} \text { are iid sequences } \\
& \mathrm{m}_{\mathrm{s}}(\mathrm{n})=\mathrm{nm} \operatorname{VAR}\left[\mathrm{~S}_{\mathrm{n}}\right]=\mathrm{n} \sigma^{2} \quad
\end{aligned}
$$

Mean and Variance are not constant but linear with time index n, thus sum process cannot be a stationary process.

Ex: 6.28 Show Random Telegraph Signal of Ex: 6.22 is stationary.
Need to show that:
$P\left[X\left(t_{1}\right)=a_{1}, \ldots, X\left(t_{k}\right)=a_{K}\right]=P\left[X\left(t_{1}+\tau\right)=a_{1}, \ldots, X\left(t_{k}+\tau\right)=a_{K}\right]$
for any $k$, any $\mathrm{t}_{1}<\cdots<\mathrm{t}_{\mathrm{k}}$, and $\mathrm{a}_{\mathrm{j}}= \pm 1$.
Since the Poisson process has the independent increments property:

$$
\begin{gathered}
P\left[X\left(t_{1}\right)=a_{1}, \ldots, X\left(t_{k}\right)=a_{K}\right]=P\left[X\left(t_{1}\right)=a_{1}\right] P\left[X\left(t_{2}\right)=a_{2} \mid X\left(t_{1}\right)=a_{1}\right] \cdots \\
P\left[X\left(t_{k}\right)=a_{k} \mid X\left(t_{k-1}\right)=a_{k-1}\right]
\end{gathered}
$$

Since the values of the random telegraph at $\mathrm{t}_{1}, \ldots, \mathrm{t}_{\mathrm{k}}$ is determined by time intervals ( $\mathrm{t}_{\mathrm{j}}, \mathrm{t}_{\mathrm{j}+1}$ ):

$$
\begin{aligned}
& P\left[X\left(t_{1}+\tau\right)=a_{1}, \ldots, X\left(t_{k}+\tau\right)=a_{K}\right] \\
& =P\left[X\left(t_{1}+\tau\right)=a_{1}\right] P\left[X\left(t_{2}+\tau\right)=a_{2} \mid X\left(t_{1}+\tau\right)=a_{1}\right] \ldots \\
& P\left[X\left(t_{k}+\tau\right)=a_{k} \mid X\left(t_{k-1}+\tau\right)=a_{k-1}\right]
\end{aligned}
$$

The transition probabilities in the above two equations are equal since

$$
\begin{aligned}
P \mid X\left(t_{j+1}\right) & \left.=a_{j+1} \mid X\left(t_{j}\right)=a_{j}\right] \\
& = \begin{cases}\frac{1}{2}\left\{1+e^{-2 \alpha\left(t_{j+1}-t_{j}\right)}\right\} & \text { if } a_{j}=a_{j+1} \\
\frac{1}{2}\left\{1-e^{-2 \alpha\left(t_{j+1}-t_{j}\right)}\right\} & \text { if } a_{j} \neq a_{j+1}\end{cases} \\
& =P\left[X\left(t_{j+1}+\tau\right)=a_{j+1} \mid X\left(t_{j}+\tau\right)=a_{j}\right]
\end{aligned}
$$

Thus they differ only in the first term

$$
P\left[X\left(t_{1}\right)=a_{1}\right] \quad \text { and } \quad P\left[X\left(t_{1}+\tau\right)=a_{1}\right]
$$

if $P[X(0)= \pm 1]=1 / 2$
then:

$$
P\left[X\left(t_{1}\right)=a_{1}\right]=1 / 2, P\left[X\left(t_{1}+\tau\right)=a_{1}\right]=1 / 2
$$

Therefore,

$$
P\left[X\left(t_{1}\right)=a_{1}, \ldots, X\left(t_{k}\right)=a_{K}\right]=P\left[X\left(t_{1}+\tau\right)=a_{1}, \ldots, X\left(t_{k}+\tau\right)=a_{K}\right]
$$

The process is stationary.
If $P[X(0)= \pm 1] \neq 1 / 2 \quad$ they are not equal.
However,

$$
\begin{aligned}
P[X(t)=a] & =P[X(t)=a \mid X(0)=a 1] \\
& = \begin{cases}\frac{1}{2}\left\{1+e^{-2 \alpha t}\right\} & \text { if } a=1 \\
\frac{1}{2}\left\{1-e^{-2 \alpha t}\right\} & \text { if } a=-1\end{cases}
\end{aligned}
$$

for small $\mathrm{t}, \mathrm{X}(\mathrm{t})$ is close to 1 ; but as t increases $\mathrm{X}(\mathrm{t})=1 \Rightarrow 1 / 2$ thus as $t$ becomes large the joint pmf's become equal. Therefore when the process settles down into "steady state" is becomes stationary.

## Wide-Sense Stationary Random Processes

A discrete-time or continuous-time random process $\mathrm{X}(\mathrm{t})$ is wide-sense stationary (WSS) if

$$
m_{X}(t)=m \quad \text { for all } t,
$$

and

$$
\mathrm{C}_{\mathrm{X}}\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right)=\mathrm{C}_{\mathrm{X}}\left(\mathrm{t}_{1}-\mathrm{t}_{2}\right) \quad \text { for all } \mathrm{t}_{1}, \mathrm{t}_{2}
$$

$\mathrm{X}(\mathrm{t})$ and $\mathrm{Y}(\mathrm{t})$ are jointly wide-sense stationary if they are both wide-sense stationary and if their cross-covariance depends only on $t_{1}-t_{2}$

$$
\mathrm{C}_{\mathrm{XY}}\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right)=\mathrm{C}_{\mathrm{XY}}(\tau) \quad \text { and } \quad \mathrm{R}_{\mathrm{XY}}\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right)=\mathrm{R}_{\mathrm{XY}}(\tau) \quad \tau=\mathrm{t}_{2}-\mathrm{t}_{1}
$$

## All stationary random processes are wide-sense stationary.

Ex: 6.29 $X_{n}$ : Two interleaved sequences of indep. random variables.
For $n$ even $X_{n}= \pm 1 \quad p=1 / 2$
For $n$ odd $X_{n}=1 / 3,-3 \quad p=9 / 10$ and $1 / 10$

$$
\begin{aligned}
& m_{X}(n)=0 \quad \text { for all } n \\
& C_{X}(i, j)=\left\{\begin{array}{lr}
E\left[X_{i}\right] E\left[X_{j}\right]=0 & i \neq j \\
E\left[X_{i}^{2}\right]=1 & i=j
\end{array}\right.
\end{aligned}
$$

Therefore, $\mathrm{X}_{\mathrm{n}}$ is wide-sense stationary.

## Properties of WSS processes:

1. Autocorrelation function at $\tau=0 \quad \Rightarrow \quad$ average power

$$
R_{X}(0)=E\left[X(t)^{2}\right] \quad \text { for all } t
$$

2. Autocorrelation function is an even function of $\tau$ :

$$
R_{X}(\tau)=E[X(t+\tau) X(t)]=E[X(t) X(t-\tau)]=R_{X}(-\tau)
$$

3. Autocorrelation function is a measure of the rate of change of random processes:

$$
\begin{aligned}
P[|X(t+\tau)-X(t)|>\varepsilon]= & P\left[(X(t+\tau)-X(t))^{2}>\varepsilon^{2}\right] \\
& \leq \frac{E\left[(X(t+\tau)-X(t))^{2}\right]}{\varepsilon^{2}} \\
& \leq \frac{2\left\{R_{X}(0)-R_{X}(\tau)\right\}}{\varepsilon^{2}}
\end{aligned}
$$

4. Autocorrelation function is maximum at $\tau=0$. Because,

$$
\begin{aligned}
& E[X Y]^{2} \leq E\left[X^{2}\right] \cdot E\left[Y^{2}\right] \\
& R_{X}(\tau)^{2}=E[X(t+\tau) X(t)]^{2} \leq E\left[X^{2}(t+\tau)\right] \cdot E\left[X^{2}(t)\right]=R_{X}(0)^{2}
\end{aligned}
$$

5. If $R_{X}(0)=R_{X}(d)$ then $R_{X}(\tau)$ is periodic with period $d$ and $X(\mathrm{t})$ is mean-square periodic i.e. $E\left[(X(t+d)-X(t))^{2}\right]=0$
6. $R_{X}(\tau)$ approaches the square of the mean of $\mathrm{X}(\mathrm{t})$ as $\tau \rightarrow \infty$

Let $\mathrm{X}(\mathrm{t})=\mathrm{m}+\mathrm{N}(\mathrm{t})$, where $\mathrm{N}(\mathrm{t})$ is a zero-mean process for which

$$
\begin{aligned}
R_{X}(\tau) & \rightarrow 0 \text { as } \tau \rightarrow \infty, \text { then } \\
R_{X}(\tau) & =E\left[(m+N(t+\tau)(m+N(t))]=m^{2}+2 m E[N(t)]+R_{N}(\tau)\right. \\
& =m^{2}+R_{N}(\tau) \rightarrow m^{2} \quad \text { as } \tau \rightarrow \infty
\end{aligned}
$$

Ex: 6.30
Fig 6.12a is autocorrelation function for random telegraph signal

$$
R_{X}(\tau)=e^{-2 \alpha|\tau|}
$$

Fig 6.12b is the autocorrelation function for a sinusoid

$$
R_{X}(\tau)=\frac{a^{2}}{2} \cos \left(2 \pi f_{0} \tau\right)
$$

Fig 6.12c is autocorrelation function for the process

$$
\mathrm{Z}(\mathrm{t})=\mathrm{X}(\mathrm{t})+\mathrm{Y}(\mathrm{t})+\mathrm{m}
$$

Where $\mathrm{X}(\mathrm{t})$ is random telegraph process, $\mathrm{Y}(\mathrm{t})$ is sinusoid with random phase, and m is constant. $\mathrm{X}(\mathrm{t})$ and $\mathrm{Y}(\mathrm{t})$ are independent.

$$
\begin{aligned}
R_{Z}(\tau) & =E[\{X(t+\tau)+Y(t+\tau)+m\}\{X(t)+Y(t)+m\}] \\
& =R_{X}(\tau)+R_{Y}(\tau)+m^{2}
\end{aligned}
$$

## Time Averages of Random Processes and Ergodic Theorems

Sometimes we are interested in estimating the mean or autocorrelation functions from the time average of a single realization

$$
\langle X(t)\rangle_{T}=\frac{1}{2 T} \int_{-T}^{T} X(t, \xi) d t
$$

and

$$
\begin{aligned}
& \operatorname{VAR}\left[\langle X(t)\rangle_{T}\right]=\frac{1}{2 T} \int_{-2 T}^{2 T}\left(1-\frac{|u|}{2 T}\right) C_{X}(u) d u \\
& \text { where } u=t-t^{\prime} \text { for }-2 T<u<2 T
\end{aligned}
$$

Let $\mathrm{X}(\mathrm{t})$ be a wide-sense stationary (WSS) process with $\mathrm{m}_{\mathrm{X}}(\mathrm{t})=\mathrm{m}$, then $\lim _{T \rightarrow \infty}\langle X(t)\rangle_{T}=m$ in the mean square sense, if and only if

$$
\lim _{T \rightarrow \infty} \frac{1}{2 T} \int_{-2 T}^{2 T}\left(1-\frac{|u|}{2 T}\right) C_{X}(u) d u=0
$$

A WSS process is said to be mean ergodic if it satisfies the above conditions.
A time-average estimate for the autocorrelation function of $\mathrm{Y}(\mathrm{t})$ is

$$
\langle Y(t+\tau) Y(t)\rangle_{T}=\frac{1}{2 T} \int_{-T}^{T} Y(t+\tau) Y(t) d t
$$

The time-average autocorrelation converges to $R_{Y}(\tau)$ in the mean square sense if $Y(t)$ is mean ergodic.

For discrete case, the mean and autocorrelation functions of $X_{n}$ are:

$$
\begin{aligned}
& \left\langle X_{n}\right\rangle_{T}=\frac{1}{2 T+1} \sum_{n=-T}^{T} X_{n} \\
& \left\langle X_{n+k} X_{n}\right\rangle_{T}=\frac{1}{2 T+1} \sum_{n=-T}^{T} X_{n+k} X_{n}
\end{aligned}
$$

If $X_{n}$ is WSS, then

$$
E\left[\left\langle X_{n}\right\rangle_{T}\right]=m \quad \text { and } \quad \operatorname{VAR}\left[\left\langle X_{n}\right\rangle_{T}\right]=\frac{1}{2 T+1} \sum_{k=-2 T}^{2 T}\left(1-\frac{|k|}{2 T+1}\right) C_{X}(k)
$$

$\left[\left\langle X_{n}\right\rangle_{T}\right]$ is mean ergodic if $\operatorname{VAR}\left\lfloor\left\langle X_{n}\right\rangle_{T}\right\rfloor$ approaches zero with increasing T.

## Ex: 6.43 Random Telegraph Process

$$
\begin{aligned}
& C_{X}(\tau)=e^{-2 \alpha|\tau|} \\
& \operatorname{VAR}\left[\langle X(t)\rangle_{T}\right]=\frac{1}{2 T} \int_{0}^{2 T}\left(1-\frac{u}{2 T}\right) e^{-2 \alpha u} d u<\frac{1}{2 T} \int_{0}^{2 T} e^{-2 \alpha u} d u=\frac{1-e^{-4 \alpha T}}{2 \alpha T}
\end{aligned}
$$

as $\mathrm{T} \rightarrow \infty \operatorname{VAR}\left[\langle X(t)\rangle_{T}\right] \rightarrow 0$, thus process is mean ergodic.

E[X(t)] & =E[A \cos w t+B \sin w t] \\
& =E[A] \cos w t+E[B] \sin w t=0 \\
C_{X}\left(t_{1}, t_{2}\right) & =E\left[\left(A \cos w t_{1}+B \sin w t_{1}\right)\left(A \cos w t_{2}+B \sin w t_{2}\right)\right]
\end{aligned}
$$

$$
\begin{aligned}
& C_{X}\left(t_{1}, t_{2}\right)= E\left[A^{2}\right] \cos w t_{1} \cos w t_{2}+E\left[B^{2}\right] \sin w t_{1} \sin w t_{2} \\
&+E[A] E[B] \cos w t_{1} \sin w t_{2}+E[A] E[B] \sin w t_{1} \cos w t_{2} \\
&= E\left[A^{2}\right] \cos w t_{1} \cos w t_{2}+E\left[B^{2}\right] \sin w t_{1} \sin w t_{2} \\
&=E\left[A^{2}\right] \underbrace{\cos w t_{1} \cos w t_{2}+\sin w t_{1} \sin w t_{2}}_{\frac{1}{2} \cos w\left(t_{1}-t_{2}\right)}\} \\
& \text { where we assumed } \quad E\left[A^{2}\right]=E\left[B^{2}\right] \\
&= \frac{1}{2} E\left[A^{2}\right] \cos w\left(t_{1}-t_{2}\right)=\frac{1}{2} E\left[A^{2}\right] \cos w \tau \\
& \therefore \mathbf{X ( t )} \text { is WSS }
\end{aligned}
$$

b) Show $\mathrm{X}(\mathrm{t})$ is not strictly-stationary

$$
\begin{aligned}
E\left[X^{3}(t)\right]= & E\left[(A \cos w t+B \sin w t)^{3}\right] \\
= & E\left[A^{3} \cos ^{3} w t+3 A^{2} B \cos ^{2} w t \sin w t+3 A B^{2} \cos w t \sin ^{2} w t\right. \\
& \left.+B^{2} \sin ^{3} w t\right] \\
= & \left.E\left[A^{3}\right] \cos ^{3} w t+E\left[B^{3}\right] \sin ^{3} w t=E\left[A^{3}\right] \cos ^{3} w t+\sin ^{3} w t\right) \\
= & \frac{E\left[A^{3}\right]}{4} \underbrace{\{3(\cos w t+\sin w t)+(\cos 3 w t-\sin 3 w t)\}}_{\text {these terms depend on } t \operatorname{explicitly}}
\end{aligned}
$$

moment of $\mathrm{X}(\mathrm{t})$ depends explicitly on time-origin

$$
\Rightarrow \quad \mathrm{X}(\mathrm{t}) \text { is not strictly-stationary }
$$

\#6.78 Find variance of Example 6.42 page 379.

$$
\begin{gathered}
\mathrm{X}(\mathrm{t})=\mathrm{A} \quad \text { A is zero mean, unit-variance r.v. } \\
E[X(t)]=E[A]=0 \\
E\left[X\left(t_{1}\right) X\left(t_{2}\right)\right]=E\left[A^{2}\right]=1 \\
\operatorname{VAR}\left[\langle X(t)\rangle_{T}\right]=\frac{1}{2 T} \int_{-2 T}^{2 T}\left(1-\frac{|u|}{2 T}\right) C_{X}(u) d u=2 \cdot \frac{1}{2 T} \int_{0}^{2 T}\left(1-\frac{u}{2 T}\right) d u=1
\end{gathered}
$$

$$
\Rightarrow \quad \text { This process is not mean-ergodic }
$$
